Feb, 2006 (first version)

Aug, 2007 (last update)

<http://www.csc.ncsu.edu/faculty/xie/publications/writepapers.pdf>

Typical Paper Structure

- Title
- Abstract
- Introduction
- Optional: Background
- Related Work (alternatively put before conclusion)
- Example
- Approach/Framework
- Implementation
- Evaluation
 - Experiment/Case Studies/Experiences/Examples
- Discussion
- Conclusions (and Future work)

Title and Abstract

- Title writing pitfall:
 - Don't put uncommon buzzwords there
 - Otherwise, bad for paper search engines or readers who would like to understand what the paper is about by reading the title
 - Be specific enough but not too specific (related to the previous bullet)
- Abstract structure:
 - Short motivation (problem); Proposed solution; Evaluation; Evaluation results
- Abstract writing pitfall:
 - Don't put unexplained or undefined terms whose meanings are not well known
 - Solutions: explain them; rephrase them using plain words; not get into too much detail (without mentioning them).

Introduction Structure

- Long motivation, problem to be solved, why existing solutions are not sufficient (sometimes examples help)
- Proposed solution and brief summary
- Optional: brief mention of related work if it is very related and explain differences
- Evaluation and evaluation results
- Optional: “The paper makes the following main contributions: + bulleted items”
 - Easy for reviewers to spot out major contributions
- Structure layout of the paper (you want to give readers high level ideas how different parts are related to each other)
 - Similar principle applied throughout the paper for subsections

Introduction –cont.

- Don't overclaim (even throughout the paper)!
 - But it is good to put your work in a bigger picture and a larger background
- Similarly don't over-criticize other's work (even throughout the paper)!
- If you want to claim some unjustified points, it is better to put them in conclusion or discussion section
- Even if so, be careful on wording
 - X “Our approach provides a foundation for this new field.”
 - “*We believe* our approach *can* provide a foundation...”
 - “*We believe* our approach *has a good potential* for providing a foundation ...”

Introduction –cont.

- Another example: be careful on wording
 - X “Our/X’s approach is the only/first one on”
 - “*With the best of our knowledge*, our/X’s approach is the only one/first on ...”
 - “Our/X’s approach is one of the/a few approaches ...”
 - “Our/X’s approach is a major/representative approach ...”
- Some reviewers don’t like you to claim your own approach to be “novel” (at least don’t put “novel” in your paper title!) – they said novelty is to be judged by them not to be claimed by you
 - “TestEra: A Novel Framework for Automated Testing of Java Programs” → “TestEra: Specification-based Testing of Java Programs Using SAT”

Stirewalt's 5-paragraph rule on writing Introduction - 1

- Introductory paragraph: Very briefly: What is the problem and why is it relevant to the audience attending *THIS CONFERENCE*? Moreover, why is the problem hard, and what is your solution? You must be brief here. This forces you to boil down your contribution to its bare essence and communicate it directly.

Stirewalt's 5-paragraph rule on writing Introduction – 2/3

- Background paragraph: Elaborate on why the problem is hard, critically examining prior work, trying to tease out one or two central shortcomings that your solution overcomes
- Transition paragraph: What keen insight did you apply to overcome the shortcomings of other approaches? Structure this paragraph like a syllogism: Whereas P and $P \Rightarrow Q$, infer Q.

Stirewalt's 5-paragraph rule on writing Introduction – 4/5

- Details paragraph: What technical challenges did you have to overcome and what kinds of validation did you perform?
- Assessment paragraph: Assess your results and briefly state the broadly interesting conclusions that these results support. This may only take a couple of sentences. I usually then follow these sentences by an optional overview of the structure of the paper with interleaved section callouts.

<http://www.cse.msu.edu/~chengb/Writing/intro-guidelines-stirewalt.txt>

The Stanford InfoLab's patented five-point structure for Introductions

1. What is the problem?
2. Why is it interesting and important?
3. Why is it hard? (E.g., why do naive approaches fail?)
4. Why hasn't it been solved before? (Or, what's wrong with previous proposed solutions? How does mine differ?)
5. What are the key components of my approach and results? Also include any specific limitations.

<http://infolab.stanford.edu/~widom/paper-writing.html>

Background and Related Work

- Differences between background and related work (c.f. my ASE journal 06 paper)
- You can organize related work with subsections or group them in several categories
- Don't simply list related work without RELATING to your own work!
 - keywords to use: whereas, in contrast, but, however, ...
 - “excuses” to use: “does not require specs”, “focus on different problems”, “complement with each other”, ...
 - you can describe several similar related approaches together and compare them at once with yours

Background and Related Work cont.

- Don't make unjustified unobvious criticisms on related work if you don't have experimental results to back you up.
 - But you can cite others' experiments to back you up.
- Don't overclaim your work without justification
- Don't intentionally leave out your own very related previous papers (reviewers can find them out easily)
 - maybe even need to mention them in Introduction section and explain why the new work is different
 - reviewers often try to identify a marginal/incremental paper or a “least publishable unit (LPU)” (Google this term!)
- Put in PC members' work if relevant

<http://www1.cs.columbia.edu/~kaiser/relatedwork.htm>

Related Work cont.

- Where to put the related work section
 - After the introduction/example section
 - Before the conclusion section
- After the introduction/example section
 - Pros: Immediately clear out reviewers' wonder on how the work differs from previous work
 - Cons: hard to let readers to know what you are talking about before showing the approach details
 - But it may be ok to put it after the example section (see next slide)
- Before the conclusion section
 - Pros: Now reviewers' know what your approach is about
 - Cons: reviewers keep wondering how the work differs from previous work till this point
 - But for very closely related work, you should have pointed out the differences in the introduction section

Example

- A simple example
 - Include: where it comes from; a figure listing source code; brief description
 - Throughout the paper, it is important to have illustrating examples for those places that contain “dry” descriptions of your approach
 - If you use several examples throughout the paper, you may not need a separate Example section.
- Optional/important part of the section: high level description of applying your approach on the example
 - describe inputs/outputs of your approach without getting into too much detail
 - very important if the later approach description involves heavy hard-to-understand formalisms
 - see my ASE 04 Rostra and TACAS 05 Symstra papers

Approach or Framework

- Generalize your work in an abstraction level, e.g., positioning it as a framework rather than a tool
 - What you develop should be beyond your own implementation
 - Then you are in a better position when you discuss limitations of your work
 - Inherent limitation of the framework?
 - Or limitation of your current particular implementation of the framework?
[See my ASE journal 06 paper]
 - A workflow diagram is useful for explaining your framework
- Try to separate the ideas from (a particular) concrete implementation
 - But sometimes you have to mention it a bit and refer the readers to the implementation section.
- Explain some details with examples (even if you have illustrated your high level ideas in the example section)

Implementation

- What libraries you used in your tool
 - e.g., BCEL, Daikon frontend, Soot
- Detailed implementations of each step in your framework
- List complications of implementing a certain idea and how you get around them
 - if some complications are important and general, you may move them to the framework section.

Evaluation

- (Controlled) Experiment: good for tools that don't involve human interactions within the approach
experiment writing structure:
 - Hypotheses/Questions to be answered
 - Measures you use to answer these questions (higher better?)
 - Experiment setup: a good number of subjects, some scripts, some third-party tools or reimplemented tools for comparison
 - Independent variables+dependent variables -> metrics
 - Experimental results
 - Illustrate how to read your table/diagrams (columns, x/y axis, etc.)
 - Explain what does the curve or data mean, e.g., “We observed that ...”, “The experimental results show ...”
 - Summarize your findings, remember to get back to answer the hypotheses and questions; it is ok to have an undecisive or negative answer based on the experimental results
 - Optional: discussion subsection; or you can put it as a separate section
 - Sometimes you may not include cost (time/memory) in your experimental results but you need to at least discuss the analysis cost
 - Threats to validity: internal, external, and construct (see my TSE 05 paper); sometimes may not need that fined-grained type classification

Evaluation cont.

- Case studies, experiences, and examples are often good for
 - approaches with human involvements [experiments can also involve humans though]
 - approaches whose results are hard to quantify with numbers (see my ICFEM 05 paper)
 - approaches you don't have a good enough number of subjects for controlled experiments
- Case studies
 - usually involve human subjects
 - often require careful preparation (tasks, questionnaires, interviews, etc.)
 - uncontrolled but just observe
 - lessons learned
- Feasibility studies: not directly assess or apply the approach on the real environment but give hints on feasibility
- Experiences/Examples
 - anecdotes; maybe just you are the one who are involved
 - You may use some wordings such as “Developers can click ... to look for ...”

Evaluation cont.

- Need explain evaluation results or describe your insights from the observed results rather than just describing the results
 - E.g., if some subjects' results are especially favorable or unfavorable, explain the reasons or even your hypothesis (wordings: “We suspect that ...” “We hypothesize that ...”). You may leave confirmation of these hypotheses to future work (e.g., on more experiments)
- Need describe “Experiment Designs”
 - E.g., factors (independent variables), treatments (one factor multiple treatments or one factor one treatment)
C.f. “Experimental program analysis: A new program analysis paradigm.” ISSTA 06
- Need hypothesis testing, t-testing especially if you want to say “A result is ****significantly**** better than B result”; statistically significant vs. practically significant
 - C.f. “Is mutation an appropriate tool for testing experiments?” ICSE 05

This slide made with contributions from S.C. Cheung at HKUST

Evaluation cont.

- What to be qualified as case studies? (more strict sense)
 - Must be conducted on real, uncontrolled industrial settings
 - If conducted at university settings, not qualified; then shall target at the experiment type (with a good number of samples); sometimes it may not be feasible to get a good number, can alleviate by writing if you can cite a pervious significant paper and state try your best to reach or go beyond their sample size; reviewers may be reasonable on it
- Case studies may also need hypothesis; in journals, even additionally need “rival hypothesis”
 - Different from “null hypothesis vs. alternative hypothesis” in experiments
http://www.stats.gla.ac.uk/steps/glossary/hypothesis_testing.html
C.f. “Statistical significance testing—a panacea for software technology experiments?” Miller JSS 04
 - E.g., Hypothesis: quality increases due to software inspection
Rival Hypothesis: quality increases due to better working environments
 - C.f. Yin’s book on Case Study Research

This slide made with contributions from S.C. Cheung at HKUST

Evaluation cont.

- In evaluation (experiments or case studies), we write
Research question (first)
Hypotheses (then)
- Research questions
 - Abstract, general, high level
- Hypotheses
 - Concrete, specific, often answers to the research questions
- In the experimental results, need describe how the results relate back to which hypotheses and how hypotheses relate back to which research questions

Evaluation cont.

- Some guidelines on doing/writing experiments
 - “Experimental program analysis: A new program analysis paradigm.”

Discussion

- Limitations and issues your approach/implementation currently cannot address
 - Optional: how are you going to address them in future work
- Other caveats (scope of your approach)
- It is often a good idea to list (obvious) limitations and discuss possible solutions for them rather than hiding them
 - Reviewers can often identify obvious limitations even if you don't state them; then they will criticize your work on these limitations (you often don't have a rebuttal against these criticisms in conference reviews).
 - If your paper discusses these obvious limitations as well as their potential solutions, the situation can be alleviated (it is like you have a rebuttal in your paper already before being criticized!).
- Possible applications of your approach that you haven't validated but are convincingly feasible or effective.
- See my TACAS 05 Symstra paper

Conclusions (and Future Work)

- Often easy to write conclusions
 - nothing here should surprise readers; simply summarize your contributions and findings
 - In the introduction, “We propose a new approach ...”
vs. In the conclusions, “We have proposed a new approach ...”
- You can state the broader impacts of your approach
- You can optionally describe limitations and future work here if you don't have a discussion section for them and propose future work
